

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

I dedicate

THIS LITTLE WORK

TO

J. WHITAKER HULKE, F.R.S.

**SENIOR SURGEON TO THE MIDDLESEX HOSPITAL AND TO THE
ROYAL LONDON OPHTHALMIC HOSPITAL**

IN ADMIRATION OF

HIS WORK

AS A CLINICAL TEACHER

2

PREFACE.

I HAVE here brought together, and given definite expression to, a large number of facts concerning the influence of sex in disease.

Many of these facts previously existed in what may be called the amorphous state ; others are now given for the first time.

In the opening remarks I have introduced a brief general survey of the subject. As a rule, the tables speak for themselves, but in many instances some comment seemed necessary.

This work would have been impossible but for the valuable statistical reports published by the various Hospitals herein named. I am convinced that this method of investigating disease—which, after its author, may be called the Hippocratic method—is of real importance.

When I consider the great advances recently made in biological science, and the methods by which they have been attained ; and when I compare them with what is now being done by modern pathology, I am amazed at the attitude of the latter, which, in its blind pursuit of isolated facts in ultimate analysis, to the exclusion of all others, obstinately ignores the brilliant example to which I have alluded, so largely due to the labours of our illustrious countrymen.

W. ROGER WILLIAMS.

LONDON : *November*, 1885.

THE
INFLUENCE
OF
SEX IN DISEASE.

‘It has long been known that in the vertebrate kingdom one sex bears rudiments of the various accessory parts, appertaining to the reproductive system, which properly belong to the opposite sex ; and it has now been ascertained that at a very early embryonic period both sexes possess true male and female glands.’—
DARWIN.

IN ORDER rightly to understand the significance of sex, we must first of all realise the highly important fact that the earliest and most primitive sexual relation was hermaphroditism ; and that the separation of the sexes, as they at present exist, was only secondarily effected, by division of labour, in the gradual progress of evolution.

All organisms, as Lamarck was the first to show, are prone to vary in consequence of ever-varying changes in the environment ; or, as Herbert Spencer puts it, life is but the continuous adjustment of internal relations to external relations.

In estimating the significance of sex, due allowance must be made for causes coming under this head.

But it is chiefly in consequence of sexual selection that male animals have been rendered so widely different from their females ; and that they tend to vary, anatomically and pathologically, in a different manner. Thus were developed

the so-called 'secondary sexual characters'—that is, those differences in the male and female sexes which appear not in the sexual organs themselves, but in other parts of the body, such as the beard of man and the breast of woman. Independently of selection, however, something must be allowed for inherent constitutional differences.

It is a very remarkable fact that in every female all the secondary male characters, and in every male all the secondary female characters, exist in a latent state, ready to be evolved under certain conditions.

Thus the females of many animals, when old, sometimes assume, more or less completely, the secondary male characters of their species; and it occasionally happens that morbid tendencies manifest a like peculiarity in their development.

In almost all countries where statistical records have been kept, the females are found to outnumber the males. This result is partly due to artificial conditions incidental to advanced civilisation.

Of the 25,974,439 persons in England and Wales, enumerated at the Census of 1881, 12,639,902 were males and 13,334,537 females. This shows an excess of 694,635 females. To each 100 males there were 105·5 females. In England the proportion of females to males has been slightly but steadily increasing during the last half-century.

This preponderance of females is all the more remarkable because the male births invariably outnumber the female births; they stand to one another in the proportion of 104 of the former to 100 of the latter.

The difference would be still greater if death struck both sexes equally before birth; but the fact is that for every 100 still-born females there are 140 still-born males (Faye). This original numerical superiority of the males is, however, soon lost, owing to their much higher death-rate, especially in early infancy. Thus it has vanished by the end of the first year of life;¹ during this period in England 126 boys die for every 100 girls. At almost every subsequent age-period, the males

¹ Vide *Registrar-General's Report of the Census of 1881*, vol. iv.

have a greater liability to death, and a higher death-rate than the females, and this in increasing proportions.

These facts are well illustrated by the subjoined table,¹ showing the comparative male and female mortality per 1,000—in 12 groups of ages—for the 41 years from 1838 to 1878.

Sex	Average	Under 5	5-10	10-15	15-20	20-25	25-35	35-45	45-55	55-65	65-75	75-85	Over 85
Males .	23'3	71	8	4	6	8	9	13	18	32	67	147	311
Females .	21'1	62	8	4	7	8	9	12	15	28	59	134	287

The superiority of woman is here well marked, except during childhood, the years of puberty, of early married life, and much child-bearing.

From the fact of this peculiarity being strongly developed during infancy, when the dress, food, and general treatment of both sexes are alike, it may be inferred that the higher male death-rate is chiefly the result of some constitutional condition inherent to sex.

As a rule women live longer than men. In his English life tables Farr estimated the mean duration of the life of males at 39'9 years, and that of females at 41'9 years.

A more recent computation has put it at 41'9 and 45'3 years respectively ; showing a gain on the former estimate of 5 per cent. for males, and of more than 8 per cent. for females. Of 89 persons, returned by the Registrar-General in the report for 1873, as dying at or over the age of 100, only 10 were males.

In England for many years past there has been a slight comparative increase in the value of female life, apparently owing to the conditions of female life being easier ; for in Belgium and Sweden, where women engage in laborious employments, the mean duration of their life is considerably shortened, so that it becomes, under these circumstances, even less than that of men.

After long study of domesticated animals, Darwin con-

¹ Beddoe, Art. 'Mortality,' *Quain's Dictionary of Medicine*.

cluded that the males were more liable to vary than the females.

Good evidence can be adduced for extending this conclusion to the two sexes of mankind. Thus Wood has found that the greater number of muscular abnormalities occur in the male sex; and of 125 cases of supernumerary digits tabulated by Wilder, 86 were males, and 39, or less than half, females.

It may be stated as a general rule that congenital defects are much commoner among males than among females. Thus there were in England, according to the Census of 1881, 133 male congenital idiots to 100 female ones.

But there are many exceptions to this rule, of which spina bifida is a good example.

Deaf-mutism and blindness, though perhaps, strictly speaking, not congenital defects, may also be mentioned here. To both of these the male liability is the greater. According to the Census of 1881, there were in England, of deaf mutes 8,043 males to 6,831 females, and of the blind, 12,048 males to 10,784 females.

Twice as many males as females die in hospitals, one cause of the excess being the great number of violent deaths among males.

In accordance with these facts, and as may be inferred from their higher death-rate, males are on the whole more liable to diseases, which are simply variations inconsistent with health, than females.

The cause of this greater general variability of the male sex is unknown. Darwin thought it might perhaps be partially accounted for by the secondary sexual characters, which are extraordinarily variable, especially in the males.

Male and female children differ less than adults in their constitution and liability to disease, as well as in other respects. On the whole, they resemble the mature female much more closely than they do the mature male.

I have no intention of entering into a detailed statement of the various diseases resulting from the anatomical peculiarities proper to each sex; although in practice it is of great

importance constantly to bear them in mind, together with the consequences they entail. I will, however, here state the most important difference between the sexes in their liability to disease, which is this: that women suffer out of all proportion from diseases of the *Generative System*, and men from diseases of the *Urinary System*.

There are in women two constitutional peculiarities not immediately attributable to sex, which it is of importance to recognise—viz. defective sanguification and a highly nervous organisation.

Exaggeration of the former of these conditions results in anæmia, debility, dyspepsia, constipation, and other gastrointestinal diseases, as well as not a few uterine and catamenial disorders.

On the other hand, it affords some protection from acute inflammatory affections, active hæmorrhages, gout, hæmophilia, aneurism, and other diseases in which atheroma is the principal lesion, to all of which women are less liable than men.

Hysteria, insanity, chorea, palpitation, goitre, migraine, neuralgia, the various forms of nervous mimicry, &c., are examples of diseases resulting from the predominance of latter condition.

Men are stronger, more passionate, more violent and intemperate than women, yet withal possessed of superior mental powers. They are also more exposed to climatic influences and to the wear and tear of life.

Hence they are more liable than women to all kinds of traumatisms, delirium tremens, alcoholism, diseases of the great arteries, kidneys, lungs, brain, bones, and joints; also to gout, rheumatism, and to sudden death.

In the subjoined table I have arranged the diseases to which each sex is the more liable in order of sequence, indicating relative liability:—

Diseases to which Females are the more liable	Diseases to which Males are the more liable	Diseases to which both sexes are equally liable
Generative system. Hysteria. Goitre and Exophthalmic goitre. Prepatellar bursitis, &c. Stricture of rectum. Chorea. Cysts. Non-malignant growths. Malignant growths. Anæmia and Debility. Lateral spinal curvature. Gastric ulcer. Anal fissure. Ascites. Peritonitis. Dropsy. Dyspepsia. Constipation. Condyloma. Quinsy and Hypertrophy of tonsils. Nasal polypus. Cancrum oris. Varix and Phlebitis. Internal and external strabismus. Glaucoma. Keratitis and Corneal ulcer. Erythema. Eczema. Psoriasis. Ulcers. Spina bifida. Whooping cough. Insanity. Ulceration and stricture of intestines. Diphtheria. Influenza. Phthisis.	Stricture of urethra. Gonorrhœal rheumatism. Stone in bladder. Angina pectoris. Tetanus. Locomotor ataxy. Alcoholism. Traumatism. Cystitis. Gout. Hydrophobia. Addison's disease. Aneurism and Atheroma. Carbuncle. Ischio-rectal abscess and Fistula-in-ano. Nephritis. Diabetes. Gangrene. Pleurisy and Empyema. Pneumonia. Asthma. Croup. Rickets. Non-strangulated hernia. Cirrhosis of liver. Ileus. Necrosis and Caries. Periostitis and Ostitis. Coxalgia. Pulpy disease of joints. Synovitis and Arthritis. Abscesses. Angular spinal curvature. Chronic lymphadenitis. Thrush. Erysipelas. Sudden death. Hydrocephalus. Laryngitis. Small-pox. Measles. Convulsions. Scarlet fever. Typhoid fever. Scrofula. Boils. Hæmorrhoids. Apoplexy.	Rheumatic fever. Epilepsy. Syphilis. Cataract. Diarrhœa. Heart disease. Bronchitis. Cholera. Strangulated hernia.

In further elucidation of the subject I have compiled the subjoined tables, which, as far as I am aware, constitute the first attempt to deal with the subject in its entirety.

The Hospital Returns refer to in-patients under treatment at the Middlesex Hospital during the years 1882-77, and at St. Bartholomew's Hospital during the years 1883-78.

Of these 37,689 were surgical cases—21,350 males and 16,339 females; 22,995 were medical cases—11,159 males and 11,836 females.

The Mortality Returns are derived from the Registrar-General's report for the twenty-five years 1872-48. They refer to the total mortality from all causes during that period.

Groups of Disease	Hospital In-patients		Mortality Returns

Other zymotics . . .	17	20	798	680
Total . . .	2,019	1,524	882,531	927,224

Small-pox, measles, scarlet fever, and febricula.—It is generally stated that both sexes are equally prone to small-pox, measles, scarlet fever, and febricula. My figures do not support this conclusion; they show that males are the more liable and have the greater mortality.

¹ These cases are from a much larger field than those of the rest of the tables. (q. v. p. 11.)

Typhoid fever.—More males than females are attacked by typhoid fever; yet on the whole more females die. Of 293 cases under treatment at the Middlesex Hospital during the four years 1880–83, 157 were males and 136 females. Of the former, 13 died (8·2 per cent.); of the latter, 27 died (19·8 per cent.) This striking difference is chiefly due to the frequency of perforation in females. In these cases pregnancy had nothing to do with it. Murchison states that one sex is as liable to typhoid fever as the other. Subsequent authors have simply repeated this statement, without taking the trouble to verify it; the error therefore is widespread.

Murchison based his statement on the total number of cases of each sex under treatment at the London Fever Hospital during a given number of years. It probably means little more than that an equal number of beds were available for both sexes. My estimate is free from this objection.

Typhus fever.—Both sexes are said to be equally liable to typhus fever; but the male mortality is the greater.

Diphtheria, whooping cough, and influenza.—The liability to diphtheria, whooping cough, and influenza is decidedly the greater in females; especially is this the case with whooping cough. This relation is remarkably constant.

Carbuncle.—Men are more than twice as subject to carbuncle as women.

Rheumatic fever.—The statements usually made with regard to the relative liability of the sexes to rheumatic fever, ascribe greater proneness to it on the part of males. Of 646 cases brought together by Garrod, 345 were males and 301 females.

Of the 1,932 cases in my table, 964 were males and 968 females.

This shows that both sexes are about equally liable.

Chronic rheumatism, gonorrhœal rheumatism, chronic osteo-arthritis, lumbago, and sciatica.—Females very rarely suffer from gonorrhœal rheumatism (only about 3 per cent, of all cases are of this sex, according to my estimate).

An *acute* form of gonorrhœal rheumatism has been recently described to which females are more liable than males. To chronic rheumatism, lumbago, and sciatica females are less liable than males. Chronic osteo-arthritis, on the whole, affects both sexes equally. The non-articular variety, in which the large joints chiefly are affected—especially the hips—is said to be of more frequent occurrence in men, whilst women suffer chiefly from the poly-articular form, affecting the small joints—especially of the hand.

Gout.—With regard to gout, of 80 cases treated by Garrod, 78 were males and only 2 females. Commenting on this, Dr. Garrod says: ‘As far as my experience goes I quite agree with this estimate, my results having shown that true gout, in its well-developed articular form, is extremely rare among females; and this holds good in both hospital and private practice. To such an extent is this the case that the influence of sex becomes a diagnostic mark between gout and rheumatism, for the latter is at least as equally frequent in men as in women.’

My figures show a less pronounced distinction than is here laid down: 178 males to 25 females.

Is this an indication of increasing resemblance between our age and the degenerate period of the Roman Empire, when women gave themselves up to every kind of intemperance, and became, equally with men, the subjects of gout?

Neoplasms.—Many theories are current as to the nature of cancer and other tumours. All of them appear to me inadequate to the purpose they are intended to fulfil; sundry of them are positively misleading; none of them have a stable basis. They reflect the prevailing confusion; and its cause—the want of a clear conception of the nature of the morbid process. My views, briefly, are these:—

I regard Cancers and Tumours as new growths—that is to say, as morphological variations, comparable in their nature to the buds of plants. The further development of the bud or initial cellular mass may be either continuous or discontinuous: it may spread as ingrowth, outgrowth, or

sometimes as both. Innocent tumours I compare with ordinary buds, because they tend to reproduce the parent structure; malignant ones with the bud variations of the so-called 'sporting plants,' because their evolution manifests departure from the parent type. The varieties under each class depend on the varying degrees of evolution.

I seek the causes of these diseases in the laws of organic morphology; which, however, are but imperfectly known. Yet this much is known, that in the end all the phenomena of variation are traceable to the influence of changed and abnormal conditions of life. These conditions may be communicated to the organism either *directly*, or *indirectly* through the reproductive system. I regard the production of monstrosities as, on the whole, closely allied to tumour formation. They probably differ only in degree. By exposing the parent to certain extraordinary conditions of life, as is well known, monstrosities may be artificially produced in the offspring. This may happen without any obvious change ensuing in the parent. The morbid impulse thus generated, issues—through the parental reproductive system—as disease in the offspring. I believe the causes of cancers and other tumours will be found in unnatural conditions of life associated with advanced civilisation. The extreme susceptibility of the female reproductive system to injurious influences of this kind is a matter of great importance to the understanding of such facts as I will now proceed to state.

Neoplasms: statistics.—The development of new growths is greatly influenced by sex. Not being aware of any comprehensive statistics on this subject, embracing a sufficiently large number of cases to be perfectly reliable, I have compiled the subjoined tables, hoping by so much to make good the deficiency. For this purpose I have made an analysis of all the primary tumours—11,100 in number—under treatment at four large metropolitan hospitals during the following years: Middlesex Hospital, 17 years (1883–67); St. Bartholomew's, 11 years (1883–73); St. Thomas's, 10 years (1883–74); and University College, 12 years (1882–71). Thus:—

TABLE I.—GENERAL : ALL NEW GROWTHS.

Kind of New Growth	Total No. of cases	Males	Females	% Approx.		Appendix
				Males	Females	
Carcinoma ¹ . .	4,027	641	3,386	16	84	¹ In using the terms <i>carcinoma</i> and <i>epithelioma</i> , I have followed the classification adopted by the registrars of the hospitals, whose reports I have employed. But in this respect they are not perfectly unanimous, especially with regard to uterine cancer. ² Eighty-five per cent. of the <i>adenomas</i> were of the female breast; one was of the male breast. Of those situated elsewhere the majority were in the salivary glands (chiefly the parotid); the male liability to these was nearly double that of the female. ³ Of the <i>enchondromas</i> 42 were connected with the bones, chiefly of hand and femur—24 males and 18 females. 20 were connected with the salivary glands: 18 with the parotid and 2 with the sub-maxillary—9 males and 11 females. ⁴ Of the <i>papillomas</i> , 16 females and 1 male were of the urethra (vascular growth); 5 males and 1 female were of the bladder (villous growth). ⁵ In this group are included the following:—Epulis, M. 4, F. 32; nasal polypus, M. 12, F. 24; aural polypus, M. 5, F. 7.
Epithelioma . .	1,842	1,398	444	76	24

Neoplasms: general remarks.—The liability of females to new growths is more than twice that of males. This may be seen on reference to Table I. Of the 11,000 cases there tabulated, 3,687 are males and 7,413 females; or the percentage proportion is 33 males to 67 females.

This striking difference is entirely due to the great frequency with which, in females, the breast, uterus, and, in a less degree, the ovary, are attacked, the corresponding male organs seldom suffering.

Omitting these, the male liability would preponderate in a very decided manner; the proportion would then be 1·4 males to 1 female.

In females, 70 per cent. of *all new growths* attack the *reproductive organs*; in males, only 7 per cent.

53·8 per cent. of all new growths are cancers; 8·2 per cent. sarcomas; 28·1 per cent. non-malignant tumours; 9·9 per cent. cysts.

Cancers.—Of the 5,978 cases of cancer in Table I., 2,096 are males and 3,882 females; the proportion being 1 male to 1·85 females.

According to the Mortality Returns, which include all kinds of malignant disease, the proportion is 1 male to 2·28 females.

Of late years, however, this distinction has been less pronounced. Thus for the three years 1881–79 the proportion is 1 male to 1·98 females.

As a group, *epithelial cancers* are of more frequent occurrence in males, the numbers being 1,398 males to 444 females, or 1 female to 3·14 males.

Rodent ulcers are pretty equally distributed between the sexes.

In females, 79·1 per cent. of all *cancers* attack the reproductive organs; in males, only 9·4 per cent. These are distributed as follows:—

Locality	Males per Cent.	Females per Cent.
Breast	·73	40·58
Uterus or prostate	·26	34·9
External genitals	7·12	3·06
Testis or ovary	1·30	·6
Total	9·41	79·14

Relative liability of each sex to cancer in special localities.—For every case of cancer of the prostate there occur 244 cases of uterine cancer; and for every case of cancer of the male breast, 101 of the female breast.

In *all other situations*, except the rectum, liver, and intestines, the male liability to cancer greatly exceeds the female liability. In the *lower lip* it is 123 times as great, in the *mouth* 7 times, in the *tongue* 6 times, in the *œsophagus* 4 times, in the *skin* twice, in the *stomach* 1·6 times, and in the *external genitals* 1·27 times.

Both sexes are equally liable to cancer of the *rectum*, *liver*, and *intestines*.

Sarcomas.—Males have a greater liability to *sarcomas* and *myxomas* than females; but the difference is not very great, as may be seen on reference to Table I. In females, 20·1 per cent. of all *sarcomas* attack the reproductive organs; in males, only 6·7 per cent.

These are distributed as follows :—

Locality	Males per Cent.	Females per Cent.
Breast	·56	19·00
Uterus or prostate	·56	·28
External genitals	—	·57
Ovary or testis	5·60	·28
Total	6·72	20·13

Non-malignant growths.—The liability of females to *non-malignant growths*, as compared with males, is even greater than their liability to cancers.

Of 3,116 cases, there are 866 males to 2,250 females ; or 1 male to 2.5 females.

This excessive female liability is partly due to the same causes we have seen with regard to cancer—viz., the frequency with which the breast (255 cases) and uterus (683 cases) are involved—in all, 938 cases.

Omitting these, however, the female liability to non-malignant tumours would still be considerably in excess of the male liability : the proportion would then be 1 male to 1.5 females.

Almost every kind of non-malignant growth is of more common occurrence in the female sex. Females are ten times as liable as males to adenomas, and more than twice as liable to lipomas and fibromas.

Cysts.—The female liability to cysts is even greater than it is to non-malignant growths and cancers.

Of 1,094 cysts, there are 248 males to 846 females ; or 1 male to 3.5 females. This preponderance of females is entirely due to the frequency of *ovarian cysts*. Omitting these, each sex would be about equally liable.

Lupus.—Much unnecessary confusion has arisen owing to the lax use of the term lupus.

I understand by lupus a special kind of new growth, quite as distinct in its way as cancer or any other neoplasm, characterised by the presence of minute 'apple-jelly tubercles.' I exclude altogether from my conception of lupus the so-called lupoid ulcerations due to syphilis, struma, cancer, &c.

The disease called lupus erythematosus I regard as a transitional form between the neoplastic and inflammatory processes.

It is sufficiently distinct from lupus vulgaris to require separate consideration.

Women are more liable to it than men : of 53 cases seen by Kaposi,¹ 18 were males and 35 females. Devergie, Hutchinson, and Kaposi have between them tabulated 344 cases of lupus vulgaris ; to these I have added the 230 cases contained in my table. The result is that, of the total 574

¹ *Trans. Internat. Med. Congr.*, vol. iii., p. 166.

cases, 233 are males and 341 females, or 1 male to 1·46 females.

Phthisis.—The statements that have been made with regard to the influence of sex in the causation of phthisis are conflicting.

Louis, whose well-known work on phthisis is the great storehouse of statistical information, makes this pertinent remark, which is still to the point :—

‘The records of medicine contain, unless I deceive myself much, very few documents indeed capable of rigorously demonstrating the relative amount of tendency in the two sexes to phthisis.’

Bayle thought it destroyed about equal numbers of each sex ; but the facts collected by Louis do not support this view.

He concluded that females are more liable than males at all periods of life ; of his 127 cases, 70 were females and 57 males ; this proportion he regarded as fairly representative. On reference to the accompanying table it will be seen that more women die of phthisis than men ; and the proportion (109 to 100) is greater than is accounted for by the excess of females in the whole population.

It may be asked, what is the cause of the great excess of males among the hospital in-patients ? Dr. Farr has answered this question in one of his reports. He says, ‘What is specially remarkable in London is the high mortality of men of all ages after twenty-five. This is due to phthisis and pulmonary disease. The mortality of women in London exceeds the mortality of women in England generally : but it is in nothing like so great an extent as men.’

Scrofula.—It is difficult to speak with absolute certainty as to the influence of sex in the development of scrofula.

Although most of the facts at my disposal point in the opposite direction, I am, nevertheless, inclined to believe there is some measure of truth in what Sir Astley Cooper says on this subject in his lectures of surgery. These are his words : ‘I do not exaggerate when I say, that within the last year I have seen 500 cases of scrofulous affections ; never a day

passes over my head without my seeing a case, and frequently three or four. This very day I have seen more ; and if asked how many were boys among them, I should answer, not one. What is the reason of it? Why boys will take exercise, and thus are less liable to the complaint, whilst girls are not allowed to do so ; and if predisposed to the disease, are almost always attacked by it.' In the above table 39,440 males and 31,737 females are recorded as having died of scrofula. With the exception of phthisis, all other scrofulous affections of which I have any account are of more frequent occurrence in males. This is especially the case with fistula-in-ano, coxalgia, pulpy disease of the joints, spinal caries, hydrocephalus, tabes mesenterica, lymphadenitis, &c.

Rickets.—According to Guérin, females are more frequently affected with rickets, the proportion being 198 to 148. My table shows 39 males to 20 females, which is, I think, more in accordance with English experience.

Diabetes : Addison's disease.—Diabetes is about twice as common in men as in women ; and Addison's disease is about three times as common.

Hæmophilia.—Hæmophilia generally attacks the males of a family, leaving the females exempt.

'I do not think I have ever seen a marked tendency to hæmorrhage in a woman belonging to a bleeder family,' says Wickham Legg.

However, a few such cases have been seen by others.

Anæmia and debility.—Females are more than four times as prone to anæmia and debility as males.

The Mortality Returns on this subject are misleading. They refer for the most part to persons who died of conditions allied to starvation, and these cases ought to be classed under that heading.

Hysteria.—It has been estimated by Briquet that one-fourth of all women are affected with decided hysteria ; and that one-half of them exhibit undue nervous susceptibility, which differs but little from it.

But, although females are chiefly subject to this affection, it is by no means exclusively confined to their sex. Out of

1,000 cases collected by Briquet, 1 male was affected in proportion to 29 females. The ratio in my table is 1 to 16.

Chorea.—It is generally agreed that the female liability to chorea is about three times as great as the male liability. This very nearly coincides with my estimate—77 males to 210 females. This predominance in favour of the female sex is manifested even in early childhood, but it becomes more pronounced as life advances. Of adults who are for the first time attacked, very few are men.

Epilepsy.—There is no uniformity in the conclusions

arrived at by different authors as to the relative liability of the two sexes to epilepsy.

But all are agreed in this: that the difference either way is not very great.

According to Dr. Gowers,¹ who has analysed a large number of cases, in pure epilepsy the female liability is the greater. His were consecutive cases, taken as they came under treatment at the National Hospital for the Paralysed and Epileptic: 52 per cent. of them were females, 48 per cent. males.

On reference to the above table, it will be seen that the cases there included do not support Dr. Gowers's conclusion. Of the hospital in-patients, 185 were males, and 102 females; whilst the Mortality Returns show 29,370 male deaths to 26,741 female deaths.

Reynolds and Nothnagel found epilepsy about equally frequent in both sexes.

Hystero-epilepsy.—Hystero-epilepsy is at least twice as common in females as in males.

Insanity.—In all civilised countries, if we take equal numbers living of each sex and at all ages, there will be found more insane females than insane males. According to the Census of 1881, there then were in England 84,503 insane persons: 44,714 females and 34,789 males.

Nevertheless it is a disputed question whether more males than females go mad.

It is admitted that the excess of female lunatics is greater than is accounted for by the excess of female population: therefore some other cause must be sought to explain it.

Such a cause is supposed to be found in the presumed greater proportionate mortality of male lunatics.

Correction being made for this, it is calculated that the male liability is the greater: the exact proportion for 1881, according to the Registrar-General,² is 106·8 male lunatics to 100 female lunatics. But the Mortality Returns show that for every 100 male lunatics there die 116 female lunatics; whereas

¹ *Lancet*, vol. i., 1880, p. 315.

² *Census Report of England for 1881*, vol. iv. p. 67.

the proportion of males to females in the whole population is only 100 to 105·5.

Therefore this conclusion is evidently erroneous.

It has unfortunately been so generally adopted that I hardly expect the prevailing misapprehension will soon disappear—all disproofs notwithstanding. Nevertheless I will state the facts as they stand. The female liability to insanity is undoubtedly the greater. This is evident both from the fact that the greater proportion of insane persons actually living at any given time are of this sex, and that the female mortality from this cause is in excess of the male mortality.

This is only what we might have expected *à priori* from the greater nervous instability of women, and from the extreme susceptibility of their sexual organisation. On the other hand, the causes that drive men mad are their violent passions, their intemperate habits, and their greater exposure to the wear and tear of life.

Some forms of madness, such as congenital idiocy and general paralysis, are much commoner in the male than in the female sex.

Tetanus and hydrophobia.—Men are much more liable than women to tetanus and hydrophobia.

Of 777 cases of *tetanus* tabulated by Friedrich, Curling, and Thambuyn, 621 are males and 126 females. The male liability is therefore more than five times as great as the female liability.

These cases were nearly all of traumatic origin. I am not aware of any statistics showing the influence of sex in cases of idiopathic tetanus.

Locomotor ataxy.—The liability to locomotor ataxy is much the greater in males; of 149 cases collected by Eulenberg, only 21 were females.

Apoplexy and hemiplegia.—It is generally believed that men are more subject to apoplexy and hemiplegia than women. In the above table the returns relating to hospital in-patients strongly support this view, but it is surprising to find that the Mortality Returns indicate a contrary result.

I am unable to account for this discrepancy.

No. 4. Diseases of the Circulatory System	Hospital In-patients		Mortality Returns

Total	1,062	934	239,731	243,534

Heart disease.—Until I had completed the above table I was not aware that diseases of the heart are of commoner occurrence in women than in men; indeed I shared the usually received opinion which favours the contrary view. This table shows the proportion to be 686 females to 638 males.

With regard to *angina pectoris*, the male liability is much the greater: out of 88 cases collected by Sir John Forbes, 8 only, or 1 in 11, occurred in females.

Aneurism.—Men are so much more exposed to the exciting causes of aneurism than women, that we need not be surprised to find them suffering more frequently from this disease.

Of 551 cases of all kinds of aneurism tabulated by Crisp, more than seven-eighths occurred in men. I think this estimate gives an exaggerated idea of the relative male liability. My estimate is that about one-fifth of all cases are females.

This is the general rule, but locality makes some difference. Thus carotid aneurisms are said to be of equally frequent occurrence in both sexes, and aneurisms of the limbs are very rare among females.

Gangrene, phlebitis, and varix.—Gangrene, like aneurism, is of much more frequent occurrence in the male than in the female sex, but to phlebitis and varix females are the more prone.

Lymphadenitis.—Lymphadenitis, both in its acute and chronic form, is of commoner occurrence in males.

Goitre, cretinism, myxœdema, cachexia strumipriva, &c.—Much has been written of late about goitre, cretinism, myxœdema, cachexia strumipriva, and the thyroid functions, but I find complete silence as to the relationship between these conditions and the reproductive system.

I propose to call attention to some facts which show that this neglected relationship is in reality of the highest importance. The principle of evolution enables us to understand the intimate correlation existing between the reproductive system, the vocal apparatus—including the thyroid body—the cerebral development, and the general nutrition of the body ; in consequence of which none of these parts can undergo important changes without seriously affecting the others, especially in early life.

Darwin has adduced overwhelming evidence to show that the vocal organs were primarily used and perfected into language in correlation with the reproductive system.

According to him, some early progenitor of man first found his voice during courtship, to express various emotions then excited, such as love, hate, jealousy, triumph, &c.

Almost everyone is now agreed that man owes his mental superiority to the higher development of his brain in correlation with the continued use of language.

Passing from these general considerations to particular facts, we see that emasculation of young animals arrests the growth of the larynx, thyroid, and of the vocal cords, causing a peculiar alteration in the voice. In addition to this, the general nutrition of the body is modified: there is a tendency to obesity, and the muscles are but feebly developed. The nervous system also shows deficiency in the special psychical characters of the male sex. Eunuchs exhibit all these changes.

In thyroidless cretins, who presented the usual changes in the general nutrition of the body, sexual system, &c., Curling discovered symmetrical fatty growths of the neck.

It requires no great stretch of the imagination to think of xanthelasma and fatty tumours as the result of analogous changes.

Certainly both of these, like goitre, manifest a remarkable predilection for the female sex.

At least 90 per cent. of goitrous persons are females.

Many young women get slight swelling of the thyroid at puberty, at the catamenial period, and after coitus; this may be mistaken for goitre, which indeed occasionally develops from it.

On this subject Malgaigne remarks: 'The ancients thought that a woman's neck enlarged immediately after the first connection; and this idea has been popularly preserved to the present time. Thus some nations still measure the circumference of the bride's neck on the day and on the day after marriage. Others go farther, and pretend to be able to recognise virginity by the following proceeding. The circumference of the neck, at its middle part, is taken with a piece of string; this is then doubled into a loop, the two ends of which are held between the incisor teeth, whilst the loop itself is made to encircle the top of the head. If the thread

passes freely over the vertex, bad sign ; but if, on the contrary, the loop is too small to pass, the conclusion drawn is in favour of virginity.

‘Physiologists have disdained these popular traditions, but I must say, without wishing to attach too much importance to them, that they are not without some foundation. Thus, in the absence of goitre or any deformity whatever, I have always found the loop too small in the case of young girls of from fifteen to twenty years old, whose morals were above suspicion.

‘In women who have lived in wedlock for several years the neck is certainly larger, and it has appeared to me to have increased in size especially from the effects of pregnancy and confinements.’

The extreme susceptibility of the reproductive system to injurious and unnatural changes in the environment is now well known.

That goitrous persons are really exposed to such injurious surroundings, we have evidence not only in what is known of the history of goitrous localities—which are generally damp and *deficient in sunlight*—but also in the pale, unhealthy, and scrofulous condition of those who, more than any others, are the subjects of this disease.

The conclusion is that goitre is the result of morbid action of the reproductive system, thus induced, reacting on the thyroid body.

But the most striking example of the correlation to which I have called attention is to be found in the next stage of the downward course of the goitrous condition—viz., in the remarkable disease known as cretinism. The relationship between these two diseases has long been a puzzle to pathologists, but it is perfectly intelligible according to the view here advanced, as also are the phenomena of exophthalmic goitre (Grave’s disease).

The offspring of goitrous persons are not unfrequently cretins. It has been stated that when both parents are goitrous for two generations in succession, the offspring, being the third generation, are sure to be cretins.

Cretinism arises in the same localities and under the same conditions as goitre.

In most cretins the thyroid is absent or atrophied; the voice and speech are imperfect; the reproductive power is feeble or absent; the brain and skull are ill-developed, with consequent loss of the higher mental faculties and sometimes idiocy, as well as blindness, deaf-dumbness, &c.; whilst the general nutrition of the whole body suffers in a marked degree.

Some cretins are also goitrous; and these manifest the same tendencies, only in a less degree.

In describing, for the first time, the disease now known as myxœdema, Sir William Gull spoke of it as a cretinoid state supervening in adults, referring thereby chiefly to the peculiar modification of the general nutrition of the body, resembling that seen in cretins. Dr. Ord subsequently discovered atrophy of the thyroid in these cases, in which the mind also is affected.

To complete the demonstration, we have precisely the same cretinoid state (cachexia strumipriva) supervening after excision of the thyroid.

I am not aware of any observations as to the action of the reproductive system under the last two conditions, with the exception of one made by Dr. Ord, who stated at the Clinical Society discussion in 1883 that the first patient in whom he had studied myxœdema, twenty years previously, bore two children after the disease was well established.

Asthma, croup, pleurisy, &c.—Males are about twice as prone to asthma, croup, pleurisy, empyema, emphysema, and pneumonia as females.

Pneumonia.—Of 63 cases of acute croupous pneumonia tabulated by me, 28 were females; and of 866 cases of catarrhal pneumonia, 267 were females.

Bronchitis.—The liability to bronchitis is equal in both sexes.

Quinsy, peritonitis, constipation, &c.—Females are much more liable to the following diseases than males:—

Quinsy, hypertrophy of the tonsils, peritonitis, gastric ulcer, constipation, dyspepsia, stricture of rectum, and fissure of the anus.

Gastric ulcers.—Perforating ulcer of the stomach is a disease to which young women from 18 to 25 years of age are more liable than others.

Chronic gastric ulcer is chiefly met with in elderly males.

Congenital contraction.—Congenital contractions of the stomach are commoner in females.

Ischio-rectal abscess, fistula-in-ano, &c.—Men are nearly three times as liable to ischio-rectal abscess and fistula-in-ano as women; they have also the greater liability to ileus, typhlitis, and non-strangulated hernia.

Diarrhœa.—Both sexes are equally liable to diarrhœa and strangulated hernia.

Hernia: general remarks.—All statistics show that males are more liable to hernia than females.

After careful consideration of all the circumstances, Kingdon estimated the relative liability at 2 males to 1 female for all ages and including every variety of hernia. Malgaigne had previously computed it at 4 to 1. My table shows the proportion at 1·5 to 1, but I prefer Kingdon's estimate, as resting on a wider basis.

Inguinal and femoral.—The records of the City of London Truss Society show that inguinal hernia is much the commonest form, more than two-thirds of the total number of applicants of both sexes, for trusses for every description of hernia, being affected with inguinal hernias. Males are chiefly liable to these ruptures; with them femoral hernias are of rare occurrence, constituting, according to Bryant, only about 4 per cent. of all cases.

Females are nearly equally liable to inguinal and femoral hernias.

The general belief that they have a greatly preponderating liability to the latter is evidently erroneous, since, out of a total of 1,442 cases of all ages, Kingdon found that the majority of femoral over inguinal hernias was only 54.

As applied to *adult* females, however, this general belief is not far from the truth, since inguinal hernias are comparatively rare at that age, most of the cases originating during early life. Thus, of 193 girls under fifteen years of age, Kingdon found 184 inguinal hernias and only 9 femoral.

In women under twenty, according to Bryant, 87 cases of inguinal hernia occur to 13 of femoral; but after the age of forty this proportion is altered for 32 of inguinal to 68 of femoral.

Umbilical hernia.—Both sexes are equally liable to the congenital form of umbilical hernia so common in infants, but the acquired form which occurs in advanced life is chiefly met with in stout women.

Strangulated hernia.—Those who have previously written on this subject have contented themselves with such statements as the above. They have avoided all reference to the important question as to the relative liability of the sexes to *strangulated* hernia.

My table shows that both sexes suffer almost equally in this respect: 125 males to 115 females. This is corroborated by the Mortality Returns: 10,724 males to 10,122 females.

The influence of sex in the different varieties of *strangulated* hernia is shown in the subjoined table:—

Kind of Strangulated Hernia	Males	Females
Inguinal	114	11
Femoral	11	94
Umbilical	—	7
Ventral	--	3
Total	125	115

Hernia of the ovary.—In women it occasionally happens that the ovary is contained in the sac of an ordinary hernia, either with or without the bowel, &c. In 38 cases of this kind mentioned by Mr. Hulke¹ as collected by Englisch of Vienna, the hernia was inguinal in 27; in most of them the displacement was on the left side, and in 9 it was double. Most of the cases were of congenital origin.

Among more than 4,000 cases of inguinal hernia treated at the Truss Society, Mr. Langton found 67 cases of hernia of the ovary. This condition is not unfrequently associated with anomalies in the development of the genital organs. The uterus in these cases is generally ante-flexed and inclined to the affected side.

Doubtful cases may be diagnosed by the undue tenderness of the swelling and the peculiar sickly pain on pressure, very different from that of an ordinary hernia.

¹ Neoplasms, venereal and puerperal diseases are not included here.

Urinary diseases in general.—It is a remarkable fact in connection with diseases of the urinary system that the male liability to almost every kind of disease greatly preponderates.

Stone in the bladder.—It is usually stated that males are about twenty times as liable to stone in the bladder as females. I think this an exaggeration; my estimate says about ten times.

Total (all traumatisms) . .	6,856	2,373	178,005	62,058

The liability to fractures, dislocations, and traumatisms generally is much less in women than in men, mainly owing to the nature of their respective employments. Thus, of the hospital in-patients comprised in my table there are 6,856 males to 2,373 females, or 2·89 males to 1 female—a ratio almost identical with that shown by the Mortality Returns.

The only traumatisms to which women are more liable than men are fractures of the lower end of the radius and intracapsular ones of the neck of the femur. To both of these the female liability is more than double the male.

Of 169 fractures of the lower end of the radius tabulated by Mr. Morris, 35 were males and 114 females.¹

Of 98 intracapsular fractures of the neck of the femur included in my table, 29 were males and 69 females.

The following tables, which include *all* fractures and dislocations of the *upper extremity* under treatment at the Middlesex Hospital during the twenty-six years ending 1879,² will be found to illustrate the subject more fully than my table, which refers only to hospital in-patients :—

¹ Holmes' *System*, vol. i. p. 947.
